

# C++ Operator Precedence

The following table lists the precedence and associativity of C++ operators. Operators are listed top to bottom, in descending precedence.

Precedence	Operator	Description	Associativity
1	::	Scope resolution	Left-to-right
2	++ --	Suffix/postfix increment and decrement	
	()	Function call	
	[]	Array subscripting	
3	.	Element selection by reference	Right-to-left
	->	Element selection through pointer	
	++ --	Prefix increment and decrement	
	+ -	Unary plus and minus	
	! ~	Logical NOT and bitwise NOT	
	( type )	Type cast	
	*	Indirection (dereference)	
	&	Address-of	
4	sizeof	Size-of	Left-to-right
	new, new[]	Dynamic memory allocation	
	delete, delete[]	Dynamic memory deallocation	
	.	Pointer to member	
5	* / %	Multiplication, division, and remainder	Left-to-right
6	+ -	Addition and subtraction	
7	<< >>	Bitwise left shift and right shift	
8	< <=	For relational operators < and ≤ respectively	
	> >=	For relational operators > and ≥ respectively	
9	== !=	For relational = and ≠ respectively	
10	&	Bitwise AND	
11	^	Bitwise XOR (exclusive or)	
12		Bitwise OR (inclusive or)	
13	&&	Logical AND	
14		Logical OR	Right-to-left
15	?:	Ternary conditional <sup>[1]</sup>	
	=	Direct assignment (provided by default for C++ classes)	
	+= -=	Assignment by sum and difference	
	*= /= %=	Assignment by product, quotient, and remainder	
	<<= >>=	Assignment by bitwise left shift and right shift	
	&= ^=  =	Assignment by bitwise AND, XOR, and OR	
16	throw	Throw operator (for exceptions)	Left-to-right
17	,	Comma	

[1]The expression in the middle of the conditional operator (between ? and :) is parsed as if parenthesized: its precedence relative to ?: is ignored.

When parsing an expression, an operator which is listed on some row will be bound tighter (as if by parentheses) to its arguments than any operator that is listed on a row further below it. For example, the expressions `std::cout<<a&b` and `*p++` are parsed as `(std::cout<<a)&b` and `*(p++)`, and not as `std::cout<<(a&b)` or `(*p)++`.

Operators that are in the same cell (there may be several rows of operators listed in a cell) are evaluated with the same precedence, in the given direction. For example, the expression `a=b=c` is parsed as `a=(b=c)`, and not as `(a=b)=c` because of right-to-left associativity.

Operator precedence is unaffected by operator overloading.

## Notes

Precedence and associativity are independent from order of evaluation.

The standard itself doesn't specify precedence levels. They are derived from the grammar.

`const_cast`, `static_cast`, `dynamic_cast`, `reinterpret_cast` and `typeid` are not included since they are never ambiguous.

Some of the operators have alternate spellings (e.g., `and` for `&&`, `or` for `||`, `not` for `!`, etc.).

Relative precedence of the conditional and assignment operators differs between C and C++: in C, assignment is not allowed on the right hand side of a conditional operator, so `e = a < d ? a++ : a = d` cannot be parsed. Many C compilers use a modified grammar where `?:` has higher precedence than `=`, which parses that as `e = ( ((a < d) ? (a++) : a) = d )` (which then fails to compile because `?:` is never lvalue in C and `=` requires lvalue on the left). In C++, `?:` and `=` have equal precedence and group right-to-left, so that `e = a < d ? a++ : a = d` parses as `e = ((a < d) ? (a++) : (a = d))`.
